

Part 1

Ans1. First of all, we can have a filter of all different positions and also candidate count for every position.

In column F and G we have source of CV & recruiter name is given, we can find how many candidates came from each source and recruiter.

Conversion rates per recruitment stage Screening --- First Round --- Second Round --- Third Round --- Hired, so basically in other words we are calculating rejection rate at every stage of interview.

One very cool insight could be count of candidate vs rejection reason. (Rejection reason can be categorized broadly as scr, 1st, 2nd and 3rd. Also, what's the hired candidate % for each recruiter.

We can find avg days b/w cv sourced and different stages, we can get an idea what's the avg days each recruitment process takes until the candidate is hired.

Also, a card we can have that shows hired ratio, hired candidates to interviewed.

Ans 2. Candidates' location, gender, educational background, **years of experience** data is missing.

Interview feedback score is missing for every stage of selection.

Ans3. In this case denormalized structure is better because it's a simple flat data with. But to make this dashboard easy to access and scalable, we can make use of facts and dimension table in a star schema, so one fact table will be there containing candidate details and foreign keys to join with dimension tables having position, dates and source it came from.

Snowflake schema is not useful because it breaks dimension into sub dimension, first of all this data is single layered, it's not that complex and also star schema will help here in data filtering.

Ans 4. Restructuring can easily be done using facts and dimensions, so what we can do is

In fact table I will store all relevant details of candidate and assign a unique id to it lets say candidate_id. This is my unique identifier. Also have some foreign key like source_id, position_id and recruitment_id which will link me with dimension tables.

Also one interesting thing here is we have dates of different stages (application date, stage 1 date, stage 2 date etc.) in recruitment we can easily join this date to date table(created by dax in power bi) and easily extract insights. Simple Structure

Please note here I am taking an assumption that we have position_id, source_id, recruitmentId as foreign keys which will join with primary keys of dimensions table, this is something normally present is in HR Analytics dashboard (as alpha numeric no.) which I have seen myself.

SOURCE OF ABOVE SCREENSHOT – Power BI File

Ans 5. Data could be cleaned first before loading it to Power BI, that's one of the practices I follow, so basically data cleaning goes through 5 stages to make sure it checks our data quality framework like consistency, relevancy, validity, accuracy and uniqueness.

But since this question has asked from Power BI perspective so we can open power query and capitalize each word. We can use proper function as well for the same, handle for null handling we can replace them with either “-” or “Unknown” or “N/A”.

We can also do trim space for any extra space left while manual entry.

Part 2

I have solved all the questions asked in Part 2, apart from this I have added my own insights as well in the dashboard like average days b/w every stage.

One thing to be noted is I found a anomaly in avg days b/w round 1 to round 2 which is coming to be negative due to some wrong input entered (can easily be detected in the chart).
